## Data-Driven Performance Analysis of Retail Coffee Sales — Afficionado Coffee Roasters

Prepared For: Unified Mentor

Prepared by: Radhika Gaddmwar

Date: September 2026

### **Purpose:**

This report presents findings from a business intelligence analysis of transactional retail sales data from Afficionado Coffee Roasters, undertaken to demonstrate how data-driven analytics can improve operational efficiency, revenue visibility, and resource allocation in small and medium retail enterprises (SMEs). The analysis is submitted as a case study in support of [digital skills development / MSME analytics adoption / retail sector modernization] initiatives.

### **Background:**

The study covers transaction-level sales data across three store locations — Astoria, Hell's Kitchen, and Lower Manhattan — spanning 80 products across 9 product categories over the reporting period. The objective was to assess whether standard analytical techniques, including revenue concentration analysis, category performance tracking, and store-level comparison, can produce actionable insight from raw retail data using accessible, low-cost tools (Python, Power BI).

## Key Findings:

| Metric                          | Finding                                                |
|---------------------------------|--------------------------------------------------------|
| Total Revenue Analyzed          | ₹6,98,812 (across all stores and categories)           |
| Stores Covered                  | 3 locations — Astoria, Hell's Kitchen, Lower Manhattan |
| Products Tracked                | 80 products across 9 categories                        |
| Top 2 Categories' Revenue Share | Coffee (38.6%) + Tea (28.1%) = 66.7%                   |
| Store Revenue Variance          | Within 3% across all three locations                   |

- **Revenue concentration:** A small subset of products (roughly 15–20 of 80) accounts for the majority of total revenue, consistent with an 80/20 distribution pattern.
- **Category dependency:** Coffee (38.6%) and Tea (28.1%) categories together generate nearly two-thirds of total revenue; the remaining seven categories contribute the balance, several below 2%.
- **Operational consistency:** Revenue performance is evenly distributed across all three store locations, within a 3% variance, indicating stable multi-site operations.
- **Volume vs. value gap:** Sales volume does not reliably predict revenue — several premium, lower-volume products significantly outperform high-volume items in revenue contribution.

## Public Interest:

Findings of this nature are directly relevant to public-sector interests in the following areas:

- **MSME resilience:** Revenue concentration risk (over-reliance on a few products) is a common vulnerability among small retailers that public support programs could address through targeted advisory services.
- **Local economic monitoring:** Store-level revenue parity suggests balanced economic activity across the surveyed micro-markets and neighborhoods.
- **Digital adoption benefit:** This case demonstrates measurable value from low-cost analytics tools for SMEs, relevant to any digital-skills or MSME-digitization support scheme.

## **Risk Consideration:**

- High dependency on a limited product set creates revenue concentration risk — a decline in a few top products could materially affect overall business stability.
- Underperforming categories (e.g., Packaged Chocolate, Loose Tea) represent inefficient use of shelf space and inventory capital with limited return.

## **Recommendation:**

1. Encourage SMEs to adopt basic revenue-concentration (Pareto) analysis as a standard business-health check.
2. Support diversification strategies for businesses showing high dependency on a narrow product range.
3. Where applicable, use this analytical framework as a template for similar SME digital-analytics capacity-building programs

## **Resource Implication:**

The analytical approach used relies on open-source and low-cost tools, requiring minimal capital investment (data collection plus basic BI training), making it a scalable model for SME-support programs.
